# Tuberculosis test reaction

TB Test Necessary? Convenient and accessAvel TB skin test TB skin test A tuberculin skin test (© m tamba called tuberculin Mantoux test) A © done to see if you already have been exposed to tuberculosis (TB). The test © done by placing a small amount of protean TB (old © domains) below the top skin layer on its inner antebraAso. If you already have been exposed to TB © s Bacta holiday (Mycobacterium tuberculosis), skin reagirA; antAgenos to developing a steady red Collision f the site within 2 days. The former © tuberculosis domains used in a tuberculin test cutaneous neo sA © E protean called the purified derivative (PPD). A measured amount of PPD in a shot © placed under the top layer of the skin in its antebraAso. This A © a good test to find the E Infection TB. Often A © used when symptoms, screening or testing, such as a chest X-ray, show that a person can have TB. TuberculAnico a test on the f can tell how long you have been infected with tuberculosis. Tamba © m at the E can tell if the Infection f o A © latent (inactive) or estA; active and can be passed to others. Why this A © made a tuberculAnico test A © made to find people who tA;m tuberculosis (TB), including: People who have been in contact with prA;ximo Aigua © m known to have TB. health professionals will likely be the E exposed to TB. People with symptoms of TB, such as a cough ongoing, sweating at night and weight loss inexplicAvel. People who have had an abnormal x-ray. People who have had a E recentA A;rA the hearing ANA transplants or tA;m Immune system, such as those of human imunodeficiAncia witha virus (HIV). A tuberculin skin test in the E should be done to people: with a infection f the known TB. Those with a serious reacAŠA E previous to the ancient domains © tuberculosis. Those with a E erupAŠA the CUTA © nea would make it difficult to read the skin test. How to prepare before having a tuberculin skin test, tell your mA © physician if you: have symptoms of tuberculosis (TB), as an ongoing cough, night sweats or weight loss inexplicAvel. They had a serious E reaAŠA a tuberculin skin test in the past. They had tuberculosis in the past. Have risk factors for TB, which sA E o things that increase your risk. Risk factors for TB include: contact with a person who has tuberculosis. A job as a health care worker who can cause you to be exposed to people with TB. Having lived or traveled in a country where TB A © common. They have been given a E vacinaAŠA TB. Thea vaccineA account © m a call Bacta © holiday BCG (bacillus Calmette-Gua A © rin) that estA; closely related to the Bacta © ria that causes tuberculosis. Were treated with drugs such as corticosterA;ides, that can affect your imunolA;gico system. E is the infected with HIV. Have a erupAŠA the CUTA E © nea that might hinder reading the skin test. Talk to your physician about any mA © preocupaAŠApes that you keep in the Interface f A need the test, its risks, as serA; done or what will be f the results. To ajudA; understand the matter © INSTANCE of this test, please complete the form Test My Information mA © dico (which A © PDF document?). As the © made for a tuberculin skin test, you sit and rotates the inner side of its antebraAso. The skin where the test © © made neat and allowed to dry. A small shot antAgeno TB (protean purified or derived from PPD) A © placed under the top layer of skin. The fluid makes a little Collision f the (caAŠa) under the skin. A cArculo can be drawn around the test A;rea with a pen. NA E o cover the site with a bandage. You should see your physician mA © 2 to 3 days aft the test have found skin test. How do you feel You may feel a sting or pinch rA;ipida needle. Risks HA; a very slight risk of having a severe to reaAŠA E tuberculin skin test, especially if you have tuberculosis (TB). A reaAŠA E winger © r;gica can cause a lot of swelling and pain at the site. An can be present. You can not get a tb tb test infection because no live bacterium is used for the test. A tuberculin skin test is safe for grasped or breastfed women. After the test, a redness on the skin test site is expected. The site can scratch, but it is important that you do not do it, itches. This can cause redness or swelling that could make it difficult to read the cutter test. IFA ItchingA, is a problem, put a cold cloth on the site and then dry it. A strong positive reaction can cause light pain. Talk to your doctor if you have: fever A. swelling in the arm. SwollenA, lymphatic greeds in Youra Axila. Results A tubercular test is done to see tuberculosis, if you have already had (tb) (infection withh, mycobacterium tuberculosis). Vermelho alone at the skin test site usually means that they were not infected with tuberculosis bacteria. A firm red collision can mean that they were infected with tuberculosis bacterial in some team. The size of the firm swelling (not red area) is measured from 2 to 3 days after the test to determine the result. Your doctor will consider your chance to have tb when looking at the skin test location. The test results depend on your risk to TB. If you are in a high risk group, a smaller collision is considered a sign of infection. People with low risk of needing tb have a greater bump from being diagnosed with a TB infection. Three levels of risk were defined: The high risk group includes people who have HIV, those who have had recent close contact with a person who has an active infection tb, and those who have symptoms or a radiography of tubing that shows tb . Other people with a high risk of tuberculosis include those taking medications that Container, Corticosteroids, for a long time or people taking biological (used for a treatan, arthritis disease arthritisa, andA, crohnA © s). From moderate risk groupa includes people who have recently changed from or traveled in a country with a high rate of TB; those who use illusions by injection (intravenous drug users); people living in nursing homes; workers in hospitals, nursing homes, schools and prisons; children under 4 years of age; Children (from 4 to 18 years) that are exposed to high-risk adults; and street locals. Others at moderate risk to tuberculosis include people who are 10% or further below their ideal body weight and people who failed Havea kidney, diabetes a, leukemia, cancer, or those who had part of them , Stomach removed (gastrectomy). Low Risk Groupa includes people who do not have any possible exposition as listed in other risk groups. A positive reaction remains normally visible for about 1 week. A positive tubercular test does not mean that you have a contagious (active) infection. The test can not tell if the infection is active or inactive (latent tb). He can also not say the difference between an TB infection and tb vaccination (BCG). More tests with such as a turbine radiography, a sputuman culture, or both fulfills to see if you have an active infection tb. What affects the test reasons you may not be able to take the test or because the results may not be atosis include: BCG vaccination (Bacillo calmette-water A © Rin). If you have already had a BCG vaccination, you can have a positive PPD cutter test, even if you do not have tb. Take medications that suppress thean, immune system, such as corticosteroids. Conditions that weaken the immune system, such as HIV cancer infection. The result can also be affected if a person is severely malnourished. Someone, vaccinations, for infections, such measles, pouch wing A, rubber, poliomyelitis, or varicella, given within 6 weeks before tuberculin test. Recent infection with one of these Virus can also interfere with test results for a short time period. The skin test can also be positive if the person has a infection caused by a mycobacteria that is not the one that causes tuberculosis. A very recent tb infection. It takes 2 to 10 weeks for the immune system reacts to tuberculosis bacteria. Age than 3 months of age. Immune system BabyA © S is not fully developed at this age. A booster Effect.A © This tends to occur in people receiving regular tha cutter tests, these workers wing healthcare .. The reinforcement effect is a weak or no reaction to the ONE tb skin tests followed by a strong reaction from a second test. But strong strong reaction The second test does not mean that the person has just become infected with TB. Instead, the reaction may be due to: infection at TB that has been a long time. Over time, a personality is immune system tends to stop the reaction strongly for tuberculosis bacterial. Thus, the first stimulates tuberculosis cutaneous test (boosts) the immunological system, which then reacts strongly with the second skin test. The BCG vaccine, which contains similar bacterials for the bacteria that cause tuberculosis. A character s immune system does not react so heavily to the vaccine bacterials, and this tends to decrease over time. Thus, the person's immunological system is reinforced by the first skin test and reacts heavily to the second test. The infection with bacterials similar tuberculosis tob, mycobacterium. This can also cause a first tb skin test to boost the immune system, allowing it to react strongly to a second test, although a new tb infection did not occur. What to think about the results of a tubercular test alone can not confirm an active infection tb. Other trials, such as an x-ray of the turbidity, cytology, andan culture, sputumA, can be done to confirm an active tb infection when a skin test is positive. A person who has a positive skin or turbulion radiography test, but they do not have symptoms of tuberculosis, usually is thought to have a tb infection that can not be passed A ©
