1, 2 and 31, and 2 Only, 1 and 3 Only, 2 and 3 Only, IIR Filter Design - Bilinear transformation method (BZT) The filter design method suffers from aliasing impulse invariance. Thus, to overcome this bilinear processing method was designed. In analog, frequency domain axis is an infinitely long straight line while Z air data samples are a ray unit of the circle. The bilinear transformation is the method of crushing the infinite analogue straight axle frequency so that it becomes finished. Important characteristics of bilinear processing method are  $\omega$ . 1. Bilinear processing method (BZT) is a mapping from analog plane on the digital Z floor. This conversion poly poly maps in digital polys and zero zero zeros. So all poles and zeros are mapped. 2. This transformation is based substantially on a numeric integration techniques used to simulate an analog filter supplement. 3. There is correspondence one to one of the continuous time and decent time frequency points. The whole range in a  $\omega$  is only mapped once in the range  $-\pi$  to  $\pi$ . 4. Frequency ratio is not linear. Frequency deformation or frequency compression is due to non-linearity. FREQUENCY FREQUENCY WIDENZE Digital filter Response is expanded to low frequencies and tablets at higher frequencies than the analog filter. 5. But the main warping frequency disadvantage is that it does not change the shape of the desired filter frequency response. In particular, the shape of the transition bands changes. Analog conversion filter in Digital filter Z is represented as reji in polar form and the ratio between the Z plane and Piano S in BZT method is given as comparing the above equation with  $s = \sigma + j\omega$ . We have here we have three conditions 1.  $\omega$ ,  $\omega$ ,  $\omega$ ,  $\omega$ ,  $\omega$ ,  $\omega$ , if i
